Modulation Calorimetry Yaakov Kraftmakher, 2013-04-18 Modulation Calorimetry reviews modulation techniques for measuring specific heat thermal expansivity temperature derivative of resistance thermopower and spectral absorptance. Owing to the periodic nature of the temperature oscillations high sensitivity and excellent temperature resolution are peculiar to all these methods. The monograph presents the various methods of the modulation and of measuring the temperature oscillations. Important applications of the modulation techniques for studying physical phenomena in solids and liquids are considered in depth: equilibrium point defects, phase transitions, superconductors, liquid crystals, biological materials, relaxation phenomena in specific heat and more. Differential Scanning Calorimetry Mike Reading, Douglas J. Hourston, 2006-02-22 MTDSC provides a step change increase in the power of calorimetry to characterize virtually all polymer systems including curing systems, blends and semicrystalline polymers. It enables hidden transitions to be revealed, miscibility to be accurately assessed and phases and interfaces in complex blends to be quantified. It also enables crystallinity in complex systems to be measured and provides new insights into melting behaviour. All of this is achieved by a simple modification of conventional DSC. In 1992 a new calorimetric technique was introduced that superimposed a small modulation on top of the conventional linear temperature program typically used in differential scanning calorimetry. This was combined with a method of data analysis that enabled the sample's response to the linear component of the temperature program to be separated from its response to the periodic component. In this way for the first time a signal equivalent to that of conventional DSC was obtained simultaneously with a measure of the sample's heat capacity from the modulation. The new information this provided sparked a revolution in scanning calorimetry by enabling new insights to be gained into almost all aspects of polymer characteristics. This book provides both a basic and advanced treatment of the theory of the technique followed by a detailed exposition of its application to reacting systems, blends and semicrystalline polymers by the leaders in all of these fields. It is an essential text for anybody interested in calorimetry or polymer characterization especially if they have found that conventional DSC cannot help them with their problems. Ye, 2015 Accurate thermophysical properties of high temperature metallic liquids are important for both industrial applications and scientific research. For the former as predictive numerical simulations play an increasingly important role in

pivotal industries such as casting welding and sintering the lack of precise thermophysical properties especially at high temperatures hamper their further applications On the other hand from the stand point of basic metals physics being able to measure calorimetric properties of liquid metallic alloys allows the calculation of their thermodynamic functions which facilitates the study of solidification kinetics of quasicrystals This research focuses mainly on measuring properties that governs heat and fluid flow namely specific heat and thermal conductivity Conventional techniques generally require test materials whether solid or liquid in direct contact with a fastener or a container which limits the application of these methods at high temperatures due to elevated thermal reactivity and also intensified heat and mass transfer To overcome these drawbacks a non contact modulation calorimetry has been developed in the 1990s Specifically a spherical sample usually smaller than 10mm in diameter is levitated using electromagnetic levitation EML in a vacuum or gas cooling atmosphere Thermophysical properties are extracted by analyzing the temperature response on the surface of the sample induced by modulated heating input This method has been proved relevant for the measurements of specific heat but is limited in thermal conductivity measurements for liquid samples because of the influence of forced convection In this study a two dimensional axisymmetrical model is developed in COMSOL Multiphysics Using magnetohydrodynamic simulation firstly the relevance of the operational principles of this method based on coupled heat flow model developed by Wunderlich et al is examined at both reported and unknown parameter range for specific heat measurements Secondly systematic error of thermal conductivity measurements using empirical equations in EML based modulation calorimetry is evaluated Lastly the possibility of combining numerical simulations and experiments to measure thermal conductivity is explored
