Optimising Supercompilers For Supercomputers:

Optimizing Supercompilers for Supercomputers Michael Joseph Wolfe, 1989 Effective use of a supercomputer requires users to have a good algorithm and to express this algorithm in an appropriate language and requires compilers to generate efficient code. This book investigates several problems facing compiler design for supercomputers including building efficient and comprehensive data dependence graphs, recurrence relations, the management of compiler temporary variables and WHILE loops. The book first proposes an efficient means of representing the flow of data in a program by labeling the arcs in a data dependence graph with direction vectors to show how the flow of data corresponds to the loop structure of the program. These data dependence direction vectors are then used in several high level compiler loop optimizations: loop vectorization, loop concurrentization, loop fusion and loop interchanging. The book shows how to perform these transformations and how to use them to optimize programs for a wide range of supercomputers. The problems of recurrence relations studied include arithmetic recurrences with IF statements and recurrences involving both data and control dependence relations in a cycle. The wavefront method of solving recurrences is also treated. The book discusses ways to make the problem of managing temporary arrays more tractable. It concludes by offering several methods for executing WHILE loops and describes a general structure of an optimizing compiler for supercomputers developed from the author's experience with a test bed compiler. Michael Wolfe is Associate Professor in the Computer Science and Engineering Department at the Oregon Graduate Center. Optimizing Supercompilers for Supercomputers is included in the series Research Monographs in Parallel Computing. Copublished with Pitman Publishing.

Optimizing Supercompilers for Supercomputers Michael Joseph Wolfe, 1982 **A Systolic Array Optimizing Compiler** Monica S. Lam, 2012-12-06 This book is a revision of my Ph D thesis dissertation submitted to Carnegie Mellon University in 1987. It documents the research and results of the compiler technology developed for the Warp machine. Warp is a systolic array built out of custom high performance processors each of which can execute up to 10 million floating point operations per second (10 MFLOPS). Under the direction of H T Kung the Warp machine matured from an academic experimental prototype to a commercial product of General Electric. The Warp machine demonstrated that the scalable architecture of high performance programmable systolic arrays represents a practical cost effective solution to the present and future computation intensive applications. The success of Warp led to the follow on iWarp project, a joint project with Intel to develop a single chip 20 MFLOPS processor. The availability of the highly integrated iWarp processor will have a significant impact on parallel computing. One of the major challenges in the development of Warp was to build an optimizing compiler for the machine. First the processors in the xx A Systolic Array Optimizing Compiler array cooperate at a fine granularity of parallelism; interaction between processors must be considered in the generation of code for individual processors. Second the individual processors themselves derive their performance from a VLIW (Very Long Instruction Word) instruction set and a high degree of internal pipelining and parallelism.

The compiler contains optimizations pertaining to the array level of parallelism as well as optimizations for the individual VLIW processors *Compiler Optimizations for Scalable Parallel Systems* Santosh Pande,Dharma P. Agrawal,2003-06-29 Scalable parallel systems or more generally distributed memory systems offer a challenging model of computing and pose fascinating problems regarding compiler optimization ranging from language design to run time systems Research in this area is foundational to many challenges from memory hierarchy optimizations to communication optimization This unique handbook like monograph assesses the state of the art in the area in a systematic and comprehensive way The 21 coherent chapters by leading researchers provide complete and competent coverage of all relevant aspects of compiler optimization for scalable parallel systems The book is divided into five parts on languages analysis communication optimizations code generation and run time systems This book will serve as a landmark source for education information and reference to students practitioners professionals and researchers interested in updating their knowledge about or active in parallel computing
