exploits hardware security features of the Intel 80x86 processor family Intel's CPU architecture provides hardware with two distinct descriptor tables. We use one of these in the usual way for process isolation. For each process the descriptor table holds the descriptors of system low segments such as code segments used by every thread in a process. We use the second table to hold descriptors for segments known to individual threads within the process. This allocation together with an appropriately designed scheduling policy permits us to avoid the full cost of process creation when only switching between threads of different security classes in the same process. Where large numbers of transactions are encountered on transaction queues this approach has benefits over traditional multilevel systems.
