Multimodal Breast Imaging Karl G. Baum, 2008 The benefit of registration and fusion of functional images with anatomical images is well appreciated in the advent of combined positron emission tomography and x ray computed tomography scanners PET CT This is especially true in breast cancer imaging where modalities such as high resolution and dynamic contrast enhanced magnetic resonance imaging MRI and F 18 FDG positron emission tomography PET have steadily gained acceptance in addition to x ray mammography the primary detection tool The increased interest in combined PET MRI images has facilitated the demand for appropriate registration and fusion algorithms A new approach to MRI to PET non rigid breast image registration was developed and evaluated based on the location of a small number of fiducial skin markers FSMs visible in both modalities The observed FSM displacement vectors between MRI and PET distributed piecewise linearly over the breast volume produce a deformed Finite Element mesh that reasonably approximates non rigid deformation of the breast tissue between the MRI and PET scans The method does not require a biomechanical breast tissue model and is robust and fast The method was evaluated both qualitatively and quantitatively on patients and a deformable breast phantom The procedure yields quality images with average target registration error TRE below 4 mm The importance of appropriately jointly displaying i e fusing the registered images has often been neglected and underestimated A combined MRI PET image has the benefits of directly showing the spatial relationships between the two modalities increasing the sensitivity specificity and accuracy of diagnosis Additional information on morphology and on dynamic behavior of the suspicious lesion can be provided allowing more accurate lesion localization including mapping of hyper and hypo metabolic regions as well as better lesion boundary definition improving accuracy when grading the breast cancer and assessing the need for biopsy Eight promising fusion for visualization techniques were evaluated by radiologists from University Hospital in Syracuse NY Preliminary results indicate that the radiologists were better able to perform a series of tasks when reading the fused PET MRI data sets using color tables generated by a newly developed genetic algorithm as compared to other commonly used schemes The lack of a known ground truth hinders the development and evaluation of new algorithms for tasks such as registration and classification A preliminary mesh based breast phantom containing 12 distinct tissue classes along with tissue properties necessary for the simulation of dynamic positron emission tomography scans was created The phantom contains multiple components which can be separately manipulated utilizing geometric transformations to represent populations or a single individual being imaged in multiple positions This phantom will support future multimodal breast
