Multithreaded Processor Design:

Multithreaded Processor Design Simon W. Moore, 2012-12-06 Multithreaded Processor Design takes the unique approach of designing a multithreaded processor from the ground up. Every aspect is carefully considered to form a balanced design rather than making incremental changes to an existing design and then ignoring problem areas. The general purpose parallel computer is an elusive goal. Multithreaded processors have emerged as a promising solution to this conundrum by forming some amalgam of the commonplace control flow von Neumann processor model with the more exotic data flow approach. This new processor model offers many exciting possibilities and there is much research to be performed to make this technology widespread. Multithreaded processors utilize the simple and efficient sequential execution technique of control flow and also data flow like concurrency primitives. This supports the conceptually simple but powerful idea of rescheduling rather than blocking when waiting for data e.g. from large and distributed memories thereby tolerating long data transmission latencies. This makes multiprocessing far more efficient because the cost of moving data between distributed memories and processors can be hidden by other activity. The same hardware mechanisms may also be used to synchronize interprocess communications to awaiting threads thereby alleviating operating system overheads. Supporting synchronization and scheduling mechanisms in hardware naturally adds complexity. Consequently existing multithreaded processor designs have tended to make incremental changes to existing control flow processor designs to resolve some problems but not others. *Multithreaded Processor Design* serves as an excellent reference source and is suitable as a text for advanced courses in computer architecture dealing with the subject.

Multithreading Architecture Mario Nemirovsky, Dean Tullsen, 2013-01-01 Multithreaded architectures now appear across the entire range of computing devices from the highest performing general purpose devices to low end embedded processors. Multithreading enables a processor core to more effectively utilize its computational resources as a stall in one thread need not cause execution resources to be idle. This enables the computer architect to maximize performance within area constraints, power constraints or energy constraints. However the architectural options for the processor designer or architect looking to implement multithreading are quite extensive and varied as evidenced not only by the research literature but also by the variety of commercial implementations. This book introduces the basic concepts of multithreading, describes a number of models of multithreading and then develops the three classic models: coarse grain, fine grain and simultaneous multithreading in greater detail. It describes a wide variety of architectural and software design tradeoffs as well as opportunities specific to multithreading architectures. Finally it details a number of important commercial and academic hardware implementations of multithreading.

Modeling and Evaluation of Multi-core

Multithreading Processor Architectures in SystemC Nicholas Ma,2007 Processor design has evolved over the years to take advantage of new technology and innovative concepts in order to improve performance Diminishing returns for improvements based on current techniques such as exploiting instruction level parallelism have caused designers to shift their focus Rather than focusing on single threaded architectures designers have increasingly sought to improve system performance and increase overall throughput by exploiting thread level parallelism through multithreaded multi core

architectures Software modeling and simulation are common techniques used to aid hardware design Through simulation different architectures can be explored and verified before hardware is actually built An appropriate choice for the level of abstraction can reduce the complexity and the time required to create and simulate software models The first contribution of this thesis is a transaction level simulation model of a multithreaded multi core processor The transaction level is a high level of abstraction that hides computational details from the designer allowing key architectural elements to be quickly explored The processor model that has been implemented for this thesis is flexible and can be used to explore various designs by simulating different processor and cache configurations The processor model is written in SystemC which is a standard design and verification language that is built on C and that can be used to model hardware systems The second contribution of this thesis is the development of an application model that seeks to characterize the behavior of instruction execution and data accesses in a program An application s instruction trace can be profiled to produce a model that can be used to generate a synthetic trace with similar characteristics The synthetic trace can then be used in place of large trace files to drive the SystemC based processor model The application model can also produce various workload scenarios for multiprocessor simulation From experimentation various processor configurations and different workload scenarios were simulated to explore the potential benefits of a multi core multithreaded processor architecture Performance increased with diminishing returns with additional multi core multithreading support However these improvement were limited by the utilization of the shared bus
