Mechanisms of Hypertension Using Mathematical Modeling and MRI Kajsa Tunedal, 2025-12-11

High blood pressure hypertension affects one third of the population and is one of the most common risk factors for cardiovascular complications such as stroke and heart failure. With correct treatment this risk can be reduced by up to 50% with as little as 5-10 mmHg reduction in blood pressure. Nevertheless, due to the complex and patient specific etiology of hypertension, more than half of all hypertensive subjects do not have a properly controlled blood pressure. To improve the treatment of hypertension, new methods and further knowledge of the patient specific mechanisms behind hypertension and its treatment are needed. One key mechanism in hypertension is the cardiovascular hemodynamics, i.e. how the heart and blood vessels regulate pressure and flow. Cardiovascular hemodynamics can be quantified using, for example, 4D flow magnetic resonance imaging (MRI), which measures blood velocity in three directions throughout the cardiac cycle. Patient specific 4D flow MRI data can be integrated with existing physiological knowledge and systems biology methods to create patient specific cardiovascular mathematical models, also known as digital twins. Digital twins can comprehensively analyze data and predict aspects of patient specific hemodynamics that cannot be directly observed, potentially aiding in patient specific diagnosis and treatment of hypertension. These aspects can be both predictions of cardiovascular function, such as central pressures or ventricular relaxation patterns, and predictions of future scenarios, such as the effects of treatments or physical activity. However, there is no digital twin for blood pressure regulation that covers short term dynamics, physical activity, and treatments in patients with hypertension. Therefore, in this thesis, I have collected new patient specific longitudinal data and combined these data with mathematical modeling to create new digital twins for cardiovascular mechanisms of hemodynamics in healthy subjects and in patients with hypertension. In the first part of the thesis, an existing cardiovascular model is applied to data from hypertensive patients, and the methods for estimating the uncertainty of the cardiovascular model are further investigated. First, in Paper I, cardiovascular digital twins were created based on subjects with either hypertension or type 2 diabetes, with both hypertension and type 2 diabetes as well as healthy controls. A comparison between the groups showed differences in biomarkers, such as left ventricular relaxation, in subjects with both diseases compared to controls and subjects with only one of the diseases. Second, in Paper II, the uncertainty of the hemodynamic data was investigated, and a novel method to estimate the uncertainty of the resulting digital twin predictions was introduced. By applying this novel method, Paper II showed that many of the biomarkers found in Paper I are reliable with a low uncertainty. In the second part of the thesis, a new study was designed to follow subjects with newly discovered hypertension from their diagnosis until a few weeks after they started their treatment. I investigated the patient specific hemodynamics of these hypertensive subjects both during physical activity (Paper III) and during drug treatment (Paper IV). In summary, this thesis introduces new methods leveraging digital twins to comprehensively investigate patient specific hemodynamic mechanisms of hypertension and its treatment. The work provides new insights into the mechanisms of hypertension and its treatment and highlights a potential path towards a personalized
