Epigenetic Control of Neural Crest Development and Evolution Megan Rothstein, 2022 Embryogenesis is characterized by the formation of a complex multicellular organism from a single pluripotent cell My thesis research has explored this phenomenon through the lens of an embryonic cell population called the neural crest Neural crest cells are a vertebrate specific cell type that gives rise to a diverse cell lineage in the developing embryo The neural crest is postulated to serve as a key driver of vertebrate evolution contributing to a number of structures in the adult body plan including the peripheral nervous system the pigmentation of the skin and the craniofacial skeleton Neural crest cell fate commitment requires not only shifts in gene expression but also an extensive remodeling of the epigenomic landscape Even so we still

have a superficial understanding of the epigenetic mechanisms which promote neural crest identity To examine the cis regulatory landscape of neural crest development I have coupled both classical embryology approaches and genomic techniques to explore cell state changes underlying neural crest identity To determine how chromatin states are reorganized during neural crest formation I examined the function of pioneer factor TFAP2A at discrete stages of development Through this work I characterized a mechanism by which TFAP2A remodels the epigenome to allow for progressive cell fate commitment within the neural crest lineage Next I aimed to understand the epigenetic basis of neural crest developmental plasticity by performing a cis regulatory comparison between two neural crest subpopulations the cranial and trunk neural crest This allowed me to identify TGF β signaling as a potent regulator of cranial neural crest identity Lastly I sought to determine how the cis regulatory landscape is modulated in neural crest cells of different species to give rise to evolutionary novelty As the craniofacial skeleton is largely derived from the neural crest I investigated the epigenetic mechanisms driving interspecific variation in beak morphology during avian embryonic development By performing single cell ATAC seq in neural crest cells isolated from three avian species chicken quail and duck I identified conserved cis regulatory regions displaying species specific accessibility and discovered a potential role for homeodomain transcription factors in modulating the neural crest epigenetic landscape across species Together these studies highlight how the epigenome shapes various aspects of cellular identity throughout development and evolution

The Neural Crest Nicole Le Douarin, Chaya Kalcheim, 1999-11-28 This 1999 edition of The Neural Crest contains comprehensive information about the neural crest, a structure unique to the vertebrate embryo which has only a transient existence in early embryonic life. The ontogeny of the neural crest embodies the most important issues in developmental biology as the neural crest is considered to have played a crucial role in evolution of the vertebrate phylum. Data that analyse neural crest ontogeny in murine and zebrafish embryos have been included in this revision. This revised edition also takes advantage of recent advances in our understanding of markers of neural crest cell subpopulations and a full chapter is now devoted to cell lineage analysis. The major research breakthrough since the first edition has been the introduction of molecular biology to neural crest research, enabling an elucidation of many molecular mechanisms of neural crest development. This book is essential reading for students and researchers in developmental biology, cell biology and neuroscience. Development and Evolution of Pigmentation Patterns in Fishes of the Genus Danio (Teleostei: Cyprinidae) Michelle M. McClure, 1998 *Genetic Correlates of Neural Crest Evolution* Daniel Keith Meulemans, California Institute of Technology. Division of Biology, 2004 Neural crest cells are unique to vertebrates and generate most of the adult structures that distinguish them from their closest invertebrate relatives, the cephalochordates. To elucidate the molecular bases of

neural crest evolution I analyzed the expression function and cis regulation of amphioxus genes with vertebrate homologs having established roles in neural crest development By comparing these amphioxus genes with their agnathan and gnathostome homologs I have uncovered genetic changes coincident with and potentially causal to the origins of neural crest I demonstrate that three transcriptional regulators involved with neural crest development AP 2 Id and SoxE were recruited to the neural plate border early in vertebrate evolution implying that genetic cooption of high order transcription factors was a major driving force in neural crest evolution I also show that the function of the Snail protein in establishing the neural plate border was not significantly altered during vertebrate evolution although vertebrate Snail genes may have evolved novel domains necessary for later functions in neural crest cells Finally I began characterizing the cis regulation of vertebrate and amphioxus Slug Snail orthologs to determine if divergent aspects of Snail gene expression i e expression in neural crest cells are reflected in structural differences in Snail cis regulatory DNA Using this 3 tiered approach I have begun to define the novel genetic regulatory interactions that drove the evolution of neural crest cells in the vertebrate lineage
