

## • Moderator

- ❑ A moderator is necessary in most reactors to slow down the fast neutrons created during fission to the thermal energy range so as to increase their efficiency in causing further fissions. The moderator must be a light material that will allow the neutrons to slow down through collisions without being captured. In most reactors, ordinary (or “light”) water is used. Other moderators used in some less common reactor types are graphite and heavy water (water formed with the heavier deuterium isotope of hydrogen). Fast reactors, based on fission of plutonium fuel by fast neutrons, do not have a moderator.

## • Coolant

- ❑ The coolant circulates through the reactor core to absorb and remove the heat produced by nuclear fission, thus maintaining the temperature of the fuel within normal limits. It transfers this heat to the turbine-generator system to produce electricity. If water is used as the coolant, steam can be produced directly by the reactor and fed to the turbines, this is the concept of a boiling water reactor. Alternatively, heated water from the reactor can be passed through heat-exchangers (steam generators) which produce steam for the turbines as in a pressurized water reactor. Other coolants in use in some reactor types are heavy water and gases such as carbon dioxide or helium. Designs for some advanced reactors use molten metals such as sodium, lead or alloys of lead as the coolant.
