R. Robinson, 2012-12-06 It is now well known that the mid ocean flow is almost everywhere dominated by so called synoptic or meso scale eddies rotating about nearly vertical axes and extending throughout the water column A typical mid ocean horizontal scale is 100 km and a time scale is 100 days these meso scale eddies have swirl speeds of order 10 cm s⁻¹ which are usually considerably greater than the long term average flow Many types of eddies with somewhat different scales and characteristics have been identified The existence of such eddies was suspected by navigators more than a century ago and confirmed by the work of C O D Iselin and V B Stockman in the 1930's Measurements from R/V Aries in 1959-60 using the then newly developed neutrally buoyant floats indicated the main characteristics of the eddies in the deep ocean of the NW Atlantic while a series of Soviet moored current meter arrays culminated in POLYGON 1970 in the explicit mapping of an energetic anticyclonic eddy in the tropical NE Atlantic In 1973 a large collaborative mainly U S U K program MODE I produced synoptic charts for an area of the NW Atlantic and confirmed the existence of an open ocean eddy field and established its characteristics Meso scale eddies are now known to be of interest and importance to marine chemists and biologists as well as to physical oceanographers and meteorologists
