Low back pain LBP is one of the most commonly reported problems in the United States The most common causes of LBP are injury or overuse pressure on neural tissue from different pathologies disc herniation stenosis degenerative disc disease etc Interbody fusion is a well established treatment option for patients with LBP For each patient the pathology and the surgeon s preference determine the surgical approach The implants are usually manufactured from either PEEK or Titanium in a variety of shapes and sizes Usually the spacers are supplemented with supplemental fixation for motion restriction However the initial surgery studies showed success for standalone scenarios without any major complications Ideally a standalone surgery that provided stability while fusion occurred could help decrease operation time and cost To this date a large scale study that compared various surgical approaches implant footprints and materials and addition of supplemental fixation has not been conducted To conduct this parametric study the experiment was separated into an in vitro and in silico study The in vitro study will allow us to record ROM data that can be used in conjunction with the in silico model to determine parameters such as stress strain and load on the endplate The in vitro study showed that a standalone PLIF surgical approach may be a viable option but the TLIF standalone case does not successfully restrict the motion to less than intact or stabilize the motion segment with peek cages However for both surgical approaches the pedicle screw fixation successfully restricted motion or stabilized the motion segment The in silico study showed that the ALIF and LLIF surgical approaches may be viable options for standalone scenarios but require further investigation Similar to the in vitro study pedicle screw greatly restricted the motion segment for all surgical approaches regardless of implant size or material property The study showed that an increase in implant footprint resulted in higher overall motion restriction for all surgical approaches The various simulated supplemental fixation stabilized the motion for all loading conditions For the anterior and lateral approaches lumbar plates provide an additional means of stabilization instead of pedicle screw fixation The study also observed that a larger implant footprint also shifted the endplate stresses to the periphery which is composed of stronger bone Overall PEEK cages produced lower endplate stresses than titanium cages which may help reduce subsidence incidence Supplemental fixation always reduced the endplate stresses compared to standalone scenarios except for some cases in the TLIF surgery The TLIF surgery also showed

higher endplate shear load when compared with other surgeries
