Excerpt from *On the Construction and Graduation of a Mortality Table* From the United States Census Thesis Introduction Before presenting the construction and graduation of the Mortality Table derived in the present paper let me call especial attention to two main facts a as far as I can find this is the first mortality table constructed from the statistics of the United States Census b the figures of this table are intended to represent as nearly as possible present day conditions in mortality rates Bearing on these two facts the following brief discussion is given of a and b a Several mortality tables have been constructed from incomplete data such as death returns physicians reports About the Publisher Forgotten Books publishes hundreds of thousands of rare and classic books Find more at [www.forgottenbooks.com](http://www.forgottenbooks.com) This book is a reproduction of an important historical work Forgotten Books uses state of the art technology to digitally reconstruct the work preserving the original format whilst repairing imperfections present in the aged copy In rare cases an imperfection in the original such as a blemish or missing page may be replicated in our edition We do however repair the vast majority of imperfections successfully any imperfections that remain are intentionally left to preserve the state of such historical works

**Construction of Mortality Tables from the Records of Insured Lives** Ray D. Murphy, 1922      **Construction of Mortality Tables From the Records of Insured Lives (Classic Reprint)** Ray D. Murphy, 2015-07-20

Excerpt from *Construction of Mortality Tables From the Records of Insured Lives* A mortality table starts with a group of persons at a specified age and shows the number of survivors at each subsequent age There is also generally set down the number dying in each year of age The radix of the table or the number living at the youngest age shown is arbitrarily selected Then from the values of  $px$  for each age the values of  $lx$  may be computed successively for the higher ages by the relation  $l_{x+1} = l_x \cdot px$  As a general rule the construction of a mortality table based on the records of insured lives is effected by ascertaining the value of  $qx$  for each age This value is obtained by dividing  $x$  by  $Ex$  where  $x$  represents the deaths and  $Ex$  the exposed to risk of death for the year between ages  $x$  and  $x + 1$  in the data under observation In practice some persons will be found who are under observation for only a part of a given year of age either because they enter the experience after the beginning of the year or because they pass out of it for causes other than death before the end of the year In such cases each person is counted in computing  $Ex$  as a fraction equal to the proportion of the year under observation The degree of accuracy with which such fractions are computed varies according to the method used in tabulating the data A person who dies between ages  $x$  and  $x + 1$  must be included in  $Ex$  as exposed to risk for the full year and not a fraction because  $qx$  represents the proportion of  $lx$  persons alive at age  $x$  who will not be alive at age  $x + 1$  About the Publisher Forgotten Books publishes hundreds of thousands of rare and classic books Find more at [www.forgottenbooks.com](http://www.forgottenbooks.com) This book is a reproduction of an important historical work Forgotten Books uses state of the art technology to digitally reconstruct the work preserving the
