Multicopper Oxidases:

Multi-copper Oxidases Albrecht Messerschmidt, 1997-06-12 The biological activation of dioxygen is a key reaction in biological systems Enzymes involved in direct oxygen activation are oxidases and oxygenases Multi copper oxidases are an important class of oxidases reducing dioxygen in a four electron reduction to water with concomitant one electron oxidation of the reducing substrate The progress in the characterization and understanding of the structure and function of these enzymes has advanced so tremendously over the last ten years that the publication of a book documenting these achievements has been overdue Especially the recent discovery of a key role of the FET3 protein of *Saccharomyces cerevisiae* a multi copper oxidase in iron metabolism of this eukaryote has underpinned the function of the plasma multi copper oxidase ceruloplasmin in vertebrate iron transport The lately determined x ray structure of human ceruloplasmin confirms its close structural relatedness to the plant multi copper oxidases ascorbate oxidase and laccase and due to strong amino acid sequence similarities has allowed to construct a useful model of the more distantly related blood clotting factor VIII This book contains review articles from experts in the field dealing with modern spectroscopy enzyme kinetics bioinorganic chemistry x ray crystallography electron transfer reactions molecular biology medical aspects and potential industrial applications of the three main members of multi copper oxidases i e laccase ascorbate oxidase and ceruloplasmin

Christopher A. Francis,2000 **Mechanistic Studies of the Multicopper Oxidases** David Earl Heppner,2014 The Multicopper Oxidases MCOs are the family of enzymes that couple the four electron reduction of dioxygen to water with four 1 electron oxidations of substrates These enzymes contain a Type 1 T1 or blue Cu center that is solvent accessible and where substrate is oxidized reducing this Cu These electrons are then transferred over a distance of 13 through the protein via a Cys His pathway to a trinuclear cluster TNC composed of a Type 3 Cu pair and a Type 2 Cu where dioxygen binds and is reduced to water The mechanism of dioxygen reduction to water by the MCOs is well characterized and proceeds in two two electron steps The fully reduced enzyme reacts with dioxygen to form the Peroxy Intermediate where dioxygen is bound as peroxide to the TNC The O O bond is cleaved at this point to produce the native intermediate NI which is fully oxidized with all three Cu s of the TNC bridged by a central oxo and the T3s are additionally bridged by a hydroxo Both moieties originate from the 4 electron reduction of dioxygen This contrasts the resting state where the only bridging ligand is a T3 hydroxo A long standing problem concerning the catalytic mechanism of the MCOs was the process by which these enzymes are rereduced in the catalytic cycle Specifically *Rhus vernicifera* Laccase exhibits a turnover rate of 560 s⁻¹ while the

intramolecular electron transfer IET from the T1 to the TNC of the resting state of this enzyme has been measured to be $1.1 \times 10^6 \text{ s}^{-1}$ and therefore not consistent with turnover. We have now experimentally determined that the reduction of NI by ET from the T1 is fast relative to its decay and obtained an IET rate lower limit of 700 s^{-1} for the first electron reduction. This proves that NI is the catalytically relevant fully oxidized form of the MCOs, not the fully oxidized resting form as studied crystallographically. Thus the first IET rate in NI reduction is more than three orders of magnitude faster than the IET rate in the resting oxidized state. Computations show that this rate difference derives from a larger driving force for proton coupled electron transfer in NI compared to the resting state due to the strong basicity of the central oxo of NI where the resting TNC site lacks a strongly basic ligand. In addition to the first IET, there are two remaining IET steps in the reduction of NI to the fully reduced state to complete the catalytic cycle. Kinetic analysis shows that the second IET step is reversible (K_{H1}), the third is irreversible, and both are fast with lower limits of 500 s^{-1} . A signal is observed in freeze quench EPR that corresponds to the 1 electron hole intermediate, two electron reduced NI. Kinetic and spectroscopic results coupled to DFT calculations reveal the mechanism of the 3 electron 3 proton reduction of NI where all three catalytically relevant intramolecular electron transfer IET steps are rapid and involve three different structural changes. The first IET process is a concerted electron and proton transfer (EPT) process made rapid due to the driving force supplied by the protonation of the basic central oxo of NI. The second IET has a low driving force but also a low reorganization energy due to a proton transfer electron transfer stepwise process. The third IET is a concerted EPT process but in this case driven by the extrusion of product waters from the fully reduced TNC. These three rapid IET processes reflect the sophisticated mechanistic flexibility of the TNC to enable rapid turnover. Importantly, all three of these IET steps are rapid because of the basicity of the dioxygen derived ligands that arise from O-O bond cleavage. In catalysis, the TNC performs the four electron reduction of dioxygen to the water level in the formation of NI, but only after NI is fully reduced are the water products of dioxygen reduction fully formed and extruded from the cluster to enable reduction of another equivalent of dioxygen. This defines a unifying catalytic mechanism for the MCOs where O-O bond cleavage and three rapid IETs are coupled to enable fast turnover in oxidation catalysis.

Meeting, H. Holden Thorp, Vincent L. Pecoraro, American Chemical Society. Division of Inorganic Chemistry, 1995. Provides an understanding of bioinorganic reactions from a mechanistic point of view. Illustrates how spectroscopy can be used to establish mechanisms and how model compounds provide mechanistic insight for enzymes. Demonstrates how to apply numerous physical methods to understanding mechanisms of redox catalysis by metal centers in enzymes. Highlights the interrelationships between the roles of metal ions in electron transfer redox catalysis, structural roles, and hydrolytic chemistry. Provides mechanistic insights into water oxidation, nitrogen fixation, nucleic acid oxidation, and hydrolysis of oxygen.
